Equivariant $sl(n)$-link homology.

For every positive integer $n$, M. Khovanov and L. Rozansky constructed a bigraded link homology theory with Euler characteristic the quantum $sl(n)$-link polynomial. Matrix factorizations played an integral part in their construction. I will discuss these theories and a generalization that is motivated by the "universal" rank two Frobenius extension studied by M. Khovanov for $sl(2)$-homology. This equivariant $sl(n)$-link homology should be a starting point of unraveling some inherent structural properties of the Khovanov-Rozasnkzy link homology and related theories.
