1145-05-949 Michael Tait* (mtait@cmu.edu). Using random polynomials in extremal graph theory. For a fixed integer k we consider the problem of how many edges may be in an n-vertex graph where no pair of vertices have t internally disjoint paths of length k between them. When t = 2 this is the notorious even cycle problem. We show that such a graph has at most $c_k t^{1-1/k} n^{1+1/k}$ edges, and we use graphs constructed via random polynomials to show that the dependence on t is correct when k is odd.
